A wiring harness may be used with a wide variety of electrical and electronic devices such as motors, relays, batteries, controls, sensors, instrumentation, etc. In many cases, a wiring harness is assembled from a plurality of electrical conductors in a desired wiring pattern by winding and crimping the conductors into a flexible outer covering or sheath. The outer covering may be molded onto the individual conductors to protect them from mechanical and environmental damage. Wiring harnesses are typically designed to accommodate some degree of length or slack between the electrical connections. For example, signal conductors of a wiring

harness may be routed to different locations and devices in a factory or other installation. Thus, for example, the signal conductor may be routed from one location to another through a machine tool, or may include a cable that extends from a motor or another device to a printed circuit board, or may include a wire that extends from a power supply to the interior of a vehicle.

In order to ensure that the signal conductors are properly connected at the end of the harness, the conductors are typically

inserted into a connector at an end of the harness and then moved to a desired location within the harness and attached. This attachment may be accomplished by crimping or other fastening means, or may be accomplished by hand soldering of wires. In many cases, connectors are mounted on the ends of wiring harnesses. The connector may be attached to the end of the wiring harness by crimping or other fastening means, and may be connected to signal conductors or other conductors in the wiring harness. Alternatively, a harness connector may be soldered to the conductors or otherwise connected to the conductors in the wiring harness. As wiring harnesses are assembled in a factory or other manufacturing location, the wiring harness may be designed to be routed to and from 82157476af
